Problem 11-1

Create a class `Employee` that has the following three instance variables:

```
String firstName
String lastName
HashMap salaryRecord
```

Do the following in your implementation of `Employee`:

1. Provide getters and setters for the `firstName` and `lastName` fields

2. The `HashMap salaryRecord` will store data about the `Employee`'s monthly paychecks. Keys in this hashtable will be dates, in the form of `String`s, and values in the hashtable will be paycheck amounts, of type `double`.

   Here is typical data that would be stored in this hashtable:

1/15/2011	3,005.50
2/15/2011	3,150.00
3/15/2011	4,200.00
4/15/2011	2,988.50

3. Implement the following three methods, according to the specification provided:

   ```
   public void addEntry(String date, double paycheckAmount)
   ```

   This method inserts into the hashtable a paycheck amount matched with a particular date

   ```
   public void printPaymentAmount(String date)
   ```

   This method will look up the paycheck stored in the hashtable, keyed on the input value of date. The output to the console should be like the following:

   ```
   Jim Jones was paid 3085.0 on 3/15/2006
   ```

   If no paycheck amount is found that matches the input date, a message should be printed that indicates this. Typical output should look like this:

   ```
   Jim Jones did not receive a paycheck on 5/15/2005
   ```

   ```
   public void printAveragePaycheck()
   ```

   This method will compute the average paycheck amount, taken over all entries in the hashtable, and then print the result to the console. Typical output should look like this:

   ```
   Average paycheck for Jim Jones was 3097.5
   ```

Note: A skeleton of the Employee class has been provided for you in the folder that goes with this lab. In that file, there is a main method which you can use to test your methods.
